MATH180C: Introduction to Stochastic Processes II

www.math.ucsd.edu/~ynemish/teaching/180c

Today: Asymptotic behaviour of renewal processes. Examples > Q&A: November 16

Next: PK 7.5, Durrett 3.1, 3.3

This week:

- Homework 6 (due Saturday, November 21, 11:59 PM)
- Quiz 4 (Wednesday, November 18, lectures 11-15)

Remark: moments of nonnegative r.v.s

Proposition. Let X be a nonnegative random variable.
Then
$$E(X^n) =$$

$$=$$

Proof. $X \geq 0 \Rightarrow X^n \geq 0$. Using the "tail" formula for the expectation of nonnegative random variables
$$E(X^n) =$$
After the change of variable $x = t^{1/n}$ we get
$$E(X^n) =$$

Remark. $M(t)$ is finite for all t

Proposition. Let $N(t)$ be a renewal process with interrenewal times X_i having distribution F. If there exist $c>0$ and $\alpha\in(0,1)$ such that $P(X_1>c)>\alpha$, then

Proof: Recall that $M(t)=\sum_{k=1}^{\infty}P(W_k\le t)=\sum_{k=1}^{\infty}P\left(\sum_{j=1}^{k}X_j\le t\right)$ $(*)$

Example: Age replacement policies (PK, p. 363)

Setting:
- component's lifetime has distribution function F
- component is replaced

  (A) either when it fails,

  (B) or after reaching age T (fixed)

  whichever occurs first
- replacements (A) and (B) have different costs:

  replacement of a failed component (A) is more expensive than the planned replacement (B)

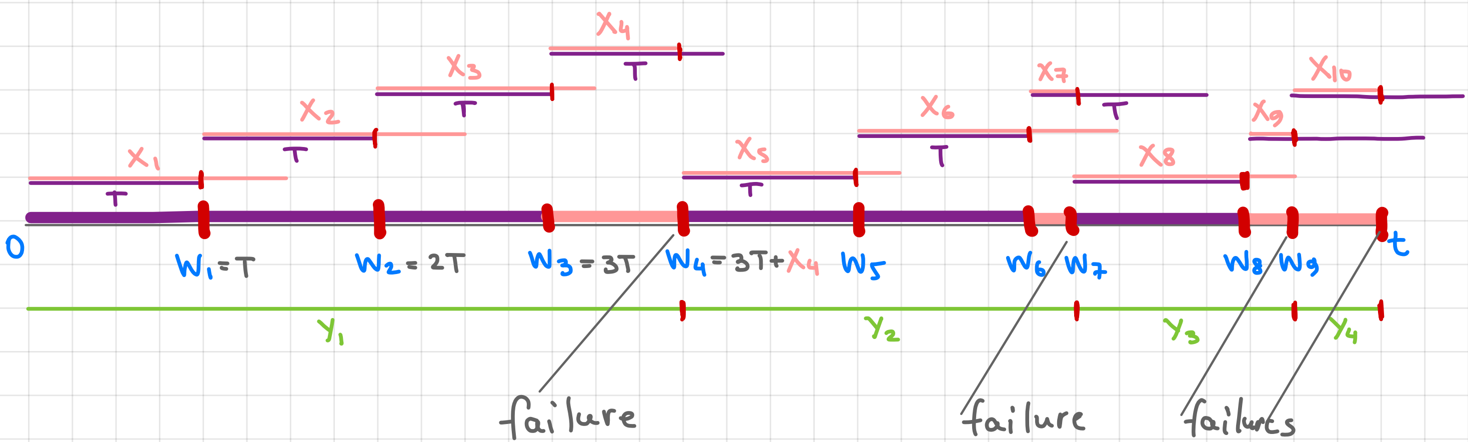
Question: How does the long-run cost of replacement depend on the cost of (A), (B) and age T?

What is the optimal T that minimizes the long-run cost of replacement?

Example: Age replacement policies (PK, p. 363)

Notation: X_i - lifetime of i-th component, $F_{X_i}(t) = F(t)$

Y_i - times between failures



Here we have two renewal processes

(1) renewal process $N(t)$ generated by renewal times $(W_i)_{i=1}^{\infty}$

(2) renewal process $Q(t)$ generated by interrenewal times $(Y_i)_{i=1}^{\infty}$

$N(t) =$, $Q(t) =$

Example: Age replacement policies (PK, p. 363)

Compute the distribution of the interrenewal times for $N(t)$

$$W_i - W_{i-1} = \begin{cases} & \\ & \end{cases}, \text{ so}$$

$$F_T(x) := P(W_i - W_{i-1} \le x) = \begin{cases} & \\ & \end{cases}$$

In particular,

$$E(W_i - W_{i-1}) =$$

Using the elementary renewal theorem for $N(t)$, the total number of replacements has a long-run rate

Example: Age replacement policies (PK, p. 363)

Compute the distribution of the interrenewal times for 🕒(t).

$$
Y_1 = \begin{cases} \qquad\qquad & \text{if } X_1 \le T \\ \qquad\qquad & \text{if } X_1 > T,\ X_2 \le T \\ \vdots & \\ \qquad\qquad , & \text{if } X_1 > T, \ldots, X_n > T,\ X_{n+1} \le T \\ \vdots & \end{cases}
$$

so

and for $z \in (0, T)$

$P(Z \le z) =$

$=$

$=$

Example: Age replacement policies (PK, p. 363)

Now we can compute the long-run rate of the replacements due to failures

$E(Y_1) =$

$E(L) =$

$E(Z) =$, so

$E(Y_1) =$

Applying the elementary renewal theorem to $Q(t)$

Example: Age replacement policies (PK, p. 363)

Suppose that the cost of one replacement is K, and each replacement due to a failure costs additional c. Then, in the long run the total amount spent on the replacements of the component per unit of time is given by

$$C(T) \approx$$

If we are given c, K and the distribution of the component's lifetime F, we can try to minimize the overall costs by choosing the optimal value of T.

Example: Age replacement policies (PK, p. 363)

For example, if $K=1$, $c=4$ and $X_1 \sim \mathrm{Unif}[0,1]$ ($F(x) = x \mathbb{1}_{[0,1]}$)

For $T \in [0,1]$, $\mu_T =$ and

the average (per unit of time) long-run costs are

$$C(T) =$$

$$\frac{d}{dT} C(T) =$$
