Today: Confidence Intervals.  
Poisson Approximation

Next: ASV 4.5

Video: Prof. Todd Kemp, Fall 2019

Week 6:

- Homework 5 (due Sunday, February 14)

## Example

Flip a fair coin  $n$  times. How does

$$\lim_{n \rightarrow \infty} P\left(\frac{\# \text{Heads}}{n} > 50.01\%\right) = 0$$

$\frac{1}{2} + 0.0001$

behave as  $n \rightarrow \infty$ ?

$$S_{D,0.01\%} \\ = 0.5001$$

$$\boxed{n = 10^{10} \quad \sqrt{n} = 10^5 \\ 2\Phi(0.0001) = 200 \\ 1 - \Phi(200) = 0} \quad \boxed{\begin{array}{l} \bar{x} = 100 \\ n = 10,000 \\ \epsilon = 0.0001 \end{array}}$$

Suppose after 10,000 flips, there are 5,001 Heads.

Should we doubt that the coin is really fair?

$$\left. \begin{array}{l} 1 - \Phi(9.02) \\ \geq 40\% \\ (49\%) \end{array} \right\}$$

$\epsilon = 0.0001$

What if, after 1,000,000 flips, there are 500,100 Heads.  
Now how confident should we be that the coin is really fair?

$$S_n = \#\text{Heads} \sim \text{Bin}(n, \frac{1}{2})$$

$$P\left(\frac{S_n}{n} \geq \frac{1}{2} + \epsilon\right) = P\left(\frac{S_n - \frac{1}{2}n}{\sqrt{n}} \geq \epsilon\right) = P\left(\frac{S_n - \frac{1}{2}n}{\sqrt{n}/2} \geq 2\epsilon\sqrt{n}\right) \approx P(X \geq 2\epsilon\sqrt{n})$$

Normal:  $\sqrt{n} \sim \sqrt{\text{Var}(S_n)} = \sqrt{n \cdot \frac{1}{2} \cdot \frac{1}{2}} = \frac{\sqrt{n}}{2}$

$$= 1 - P(X < 2\epsilon\sqrt{n}) \\ = 1 - \Phi(2\epsilon\sqrt{n})$$

# Confidence

4.3

Suppose we have a coin that is biased by some unknown amount;

$$X \sim \text{Ber}(p)$$

unknown  $p$ !

How can we figure out what  $p$  is?

Use the law of large numbers:  $p = \lim_{n \rightarrow \infty} \frac{S_n}{n}$

We can't actually wait around for  $n \rightarrow \infty$ , Instead,  
we estimate

$$p \approx \hat{p} := \frac{S_n}{n} \text{ for some large } n.$$

The question is: how good an estimate is this for given  $n$ ?  
Or, turning it around: how big must you take  $n$  to get an  
estimate of a certain accuracy?

$$|\hat{p} - p| < \varepsilon (= 0.01)$$

$$P(|\hat{p} - p| < \varepsilon) \geq 95\%$$

" $\hat{p}$  is within margin  
of error  $\varepsilon$  of  $p$ , w/  
probability 95%."

# A Maximum Likelihood Estimate

Want to find  $n$  large enough that (with  $\hat{p} = S_n/n$ )

$$P(|\hat{p} - p| < \varepsilon) \geq \text{(high probability)}$$

↑  
chosen tolerance

$$\begin{aligned} P(|\hat{p} - p| < \varepsilon) &= P\left(\frac{|S_n - np|}{\sqrt{np(1-p)}} < \frac{\varepsilon\sqrt{n}}{\sqrt{p(1-p)}}\right) \approx P\left(|X| < \frac{\varepsilon\sqrt{n}}{\sqrt{p(1-p)}}\right) \\ &= \Phi\left(\frac{\varepsilon\sqrt{n}}{\sqrt{p(1-p)}}\right) - \Phi\left(-\frac{\varepsilon\sqrt{n}}{\sqrt{p(1-p)}}\right) \end{aligned}$$

$$P(|\hat{p} - p| < \varepsilon) \approx 2\Phi\left(\frac{\varepsilon\sqrt{n}}{\sqrt{p(1-p)}}\right) - 1.$$

$$\begin{aligned} 0 < p < 1 &\quad \frac{1}{\sqrt{p(1-p)}} \geq 2 \\ p(1-p) \leq \frac{1}{4} &\quad \Phi \uparrow \\ \max @ p = \frac{1}{2} \end{aligned}$$

Conclusion:  $P(|\hat{p} - p| < \varepsilon) \geq 2\Phi(2\varepsilon\sqrt{n}) - 1$ .

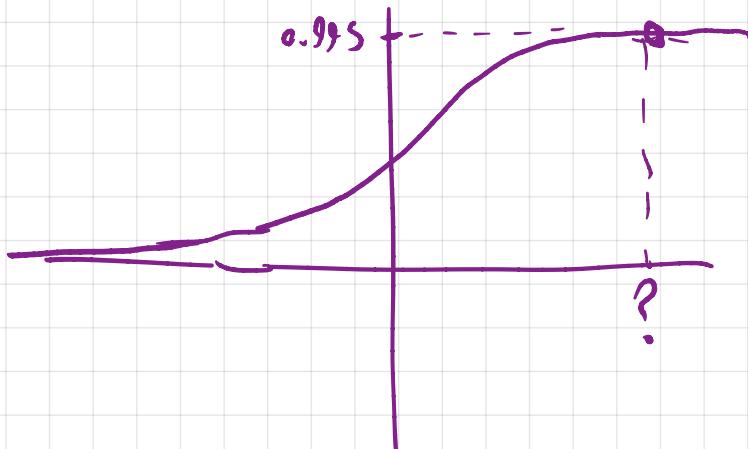

$$X \sim N(\mu, \sigma^2)$$

Example: How many times should we flip a coin, biased an unknown amount  $p$ , so that the estimate  $\hat{p} = S_n/n$  is within a tolerance of 0.05 of the true value  $p$ , with probability  $\geq 99\%$ ?

Want  $n$  large enough that

$$P(|\hat{p} - p| < 0.05) \geq 99\%$$

We know  $P(|\hat{p} - p| < 0.05) \approx 2 \Phi(2(0.05)\sqrt{n}) - 1 \geq 99\%$

makes sure

$$\Phi(2(0.05)\sqrt{n}) \geq 0.995$$

$$\therefore 2(0.05)\sqrt{n} \geq 2.58$$

$$\sqrt{n} \geq 25.8$$

$$n \geq 665.64$$

**666**

## Confidence Intervals

Turning this around: if we can't control  $n$ , we would like to say how accurate the sample mean is as an estimate of the true mean, for a given number  $n$  of samples.

E.g. A coin (of unknown bias  $p$ ) is tossed 1000 times. 450 Heads come up. Within what tolerance can we say we know the true value of  $p$  with probability  $\geq 95\%$ ?

Estimate  $p \approx \hat{p} = \frac{S_{1000}}{1000} = 0.45$

Want  $P(|p - \hat{p}| < \varepsilon) \geq 95\%$

Know:  $P(|p - \hat{p}| < \varepsilon) \geq 2\Phi(2\varepsilon\sqrt{1000}) - 1 \geq 0.95$

$\Phi(2\varepsilon\sqrt{1000}) \geq 0.975$

I.e.  $|p - 0.45| < 0.03 \Leftrightarrow P \geq 95\% \quad \left\{ \begin{array}{l} 2\varepsilon\sqrt{1000} \geq 1.96 \Rightarrow \varepsilon \geq \frac{1.96}{2\sqrt{1000}} \div 0.03 \\ p \in [0.419, 0.481] \Leftrightarrow P \geq 95\% \end{array} \right.$

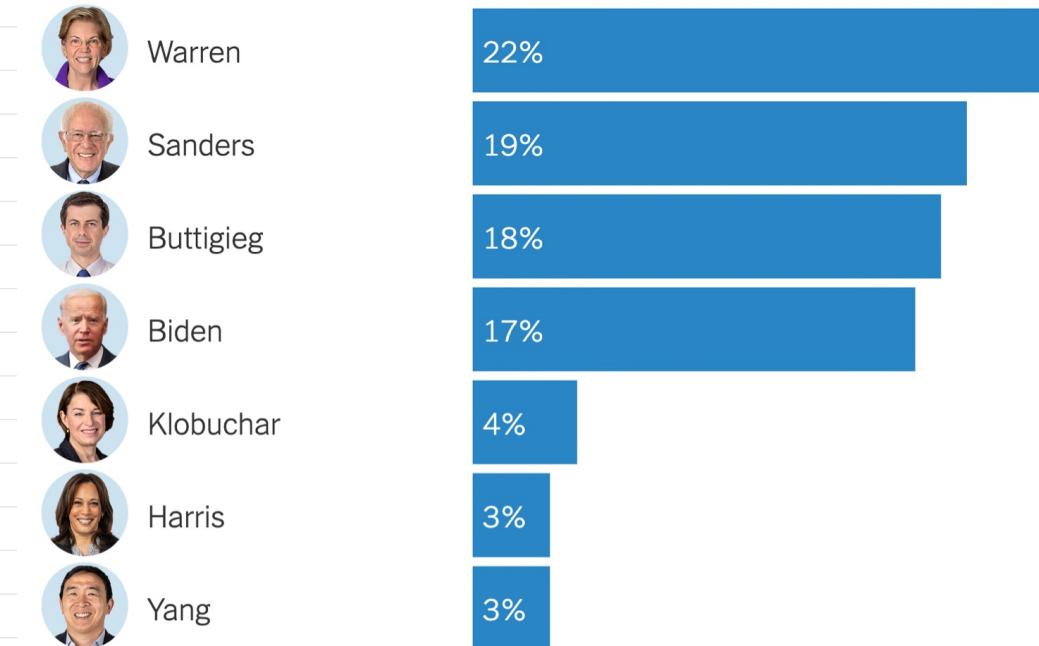

95% confidence interval

If an experiment is repeated in many independent trials, and the preceding (normal approximation) estimates yield

$$P(|\hat{p} - p| < \varepsilon) \geq 95\%$$

we say  $[\hat{p} - \varepsilon, \hat{p} + \varepsilon]$  is the 95% confidence interval for  $p$ .

The same statement might be given as " $p = \hat{p}$  with margin of error  $\varepsilon$  (95 times out of 100)".

Source: New York Times Upshot/Siena College poll conducted Oct. 25-30.

Margin of error: 4.7%

Poll conducted Oct 25-30  
of 439 Iowa Democratic  
caucusgoers.

$$P(|p - \hat{p}| < \varepsilon) \geq 2 \Phi(2\varepsilon/\sqrt{439}) - 1$$
$$_{0.22} \quad (\approx) \geq 0.95$$

$$2\varepsilon/\sqrt{439} \geq 1.96$$

$$\varepsilon \geq 4.68\%$$

# Poisson vs. Normal Approximation - Quantitative

4.4

Theorem. Let  $S_n \sim \text{Bin}(n, p)$

$$X \sim \text{Poisson}(np)$$

$$Y \sim \mathcal{N}(0, 1)$$

For any subset  $A \subseteq \mathbb{N}$ ,

$$|\mathbb{P}(S_n \in A) - \mathbb{P}(X \in A)| \leq np^2$$

OTOH, for any  $x \in \mathbb{R}$ ,

Berry-Essen Thm.

$$\left| \underbrace{\mathbb{P}\left(\frac{S_n - np}{\sqrt{np(1-p)}} \leq x\right)}_{\text{CDF of } \frac{S_n - np}{\sqrt{np(1-p)}}} - \underbrace{\mathbb{P}(Y \leq x)}_{\Phi(x)} \right| \leq \frac{3}{\sqrt{np(1-p)}}$$

3 is not optimal

optimal

Upshot: if  $np^2$  is small, use Poisson Approximation.

if  $np(1-p)$  is quite large, use Normal Approximation.

## Beyond independent trials:

- \* The normal approximation breaks down quickly if the trials are dependent.
- \* The Poisson approximation holds up well under "weak dependence"

Example. A factory experiences 3 accidents per month, on average.  
What is the probability there will be 3 accidents this month?

$X = \# \text{ accidents in a given month.}$

well modeled  
by a Poisson.

$$X \sim \text{Poisson}(\lambda)$$

$$3 = \mathbb{E}(X) = \lambda$$

$$P(X=3) = e^{-3} \frac{3^3}{3!} = 22.4\%$$

$$\frac{3^3}{3!} = \frac{3^2 \cancel{3}}{\cancel{3}^2 \cdot 1} = \frac{3^2}{2!}$$

$$P(X=2) = e^{-3} \frac{3^2}{2!} = 22.4\%$$
